

**FIGURE.** Study design. Population-level estimates of rates of emergency department (ED) visits and hospitalizations for hypoglycemia were estimated by applying hypoglycemia rate estimates for clinically complex and non-clinically complex adults receiving intensive and nonintensive glucose-lowering treatment from the observational study by McCoy et al<sup>14</sup> to participants meeting these definitions within the National Health and Nutrition Examination Survey (NHANES) sample. The shaded boxes provide data from the NHANES population-level estimate, while non-shaded boxes on the right reflect previously published data from McCoy et al on percent of patients with any hospitalization(s) or any ED visit(s) for severe hypoglycemia during a 2-year study period and the mean (SD) number of events.
